# Porcine epidemic diarrhea (PED)

# **TORs and CONCLUSIONS**

#### **TOR1 – EPIDEMIOLOGICAL SITUATION**

1/2

The current **epidemiological situation** in North America and Asia and elsewhere in the world as regard PED and the new porcine Deltacoronavirus

### **PED in Europe:**

- Only limited active monitoring is conducted.
- Only a few Member States reported PED clinical cases and/or PEDV-seropositive animals within the last 10 years.
- In 2014, some outbreaks have been reported in Germany and Italy.
- **No vaccination** has been used.

#### **TOR1 – EPIDEMIOLOGICAL SITUATION**

# **PED in Asia:**

- Only limited active monitoring is conducted.
- Many outbreaks have been reported in several countries within the last 10 years.
- Vaccination has been used in several countries, which might influence the epidemiological situation.

# **PED in the Americas:**

- Only limited active monitoring is conducted.
- The first outbreak was reported in May 2013 in the USA, followed by a rapid spread throughout the country and outbreaks reported by several countries in North, Central and South America.

In 2014, new vaccines were granted conditional licences in the USA, which may influence the epidemiological situation.

#### TOR3 - DIFFERENCES BETWEEN STRAINS1/2

Possible **differences between** the European classical PED Alphacoronavirus **strains** and the ones currently circulating in the rest of the world, in particular in the Americas, and possible existence of cross protecting immunity

- Few sequence data from PEDV-EU isolates are available, limited to historic (1970s and 1980s) and very recent (2014) cases. A high level of sequence identity was found between recent German and Italian viruses (2014) and PEDV-Am viruses.
- An original and a variant PEDV-Am strain, both having high nucleotide sequence identity to PEDV-As isolates from 2011-2012, are now co-circulating in the Americas. Retrospective studies indicate that at least two PEDV strains were introduced into the USA at a similar time.

#### TOR3 - DIFFERENCES BETWEEN STRAINS2/2

- Differences in the nucleotide sequence of PEDVs have been identified, but their effects (if any) on virulence of the virus is currently unknown. No comparative experimental studies have been conducted or reported.
- Serological cross-reactivity between PEDV-EU and PEDV-Am is reported ; however, no data regarding cross-protection are available.
- The evolution of PEDVs in Europe and the link to PEDV strains circulating in other parts of the world is not well understood at present

#### TOR4 – IMPACT

**Impact** of the different PED Alphacoronavirus strains and of the new porcine Deltacoronavirus in pigs in different immunological scenarios

- The impact of recently reported PED outbreaks in Asia (after 2010) and the US seems to be more severe than what has been recently described in Europe.
- The clinical signs of PEDV infections in naive pigs are similar in different countries indicating that different PEDV isolates induce similar clinical signs.
- The different impacts of PED outbreaks in different countries cannot be directly compared owing to variation for instance, in age group of the affected pigs, production systems, biosecurity, farm management, herd size, the immune status of the population and herd sanitary status.
- Mortality of up to 100% has been reported in suckling piglets for PEDV-EU, PEDV-Am and PEDV-As.

#### **TOR4 – IMPACT**

#### 2/2

An apparent low impact of recent PED outbreaks caused by viruses that have high sequence identity to US PEDV, has been reported in Italy and Germany. Factors which might influence the impact of a possible introduction of a US PEDV and spread of the virus to Member States include the level of cross-protection between different PEDVs and sero-prevalence (population immunity), which are currently unknown but expected to vary between Member States. The recent impact of PED in Europe needs to be interpreted with care because only a small number of outbreaks have been described.

#### **TOR5 – PRESENCE AND SURVIVAL IN MATRICES** 1/3

Risk assessment of **potential entry routes** of PED and the new porcine deltacoronavirus in the EU ranking them on the basis of the level of risk with a view to enhance risk mitigation, prevention and preparedness

- Infected live animals and faeces have been reported to transmit PEDV. The infectious virus can survive in slurry, but at present there are no data available on the role of this matrix in PEDV transmission.
- High levels of infectious PEDV are shed in faeces and contribute to contamination of various objects (e.g. vehicles, humans) and feed.
- The transmission of PEDV via feed has been shown but more data are required to assess the importance of PEDV spread via feed.

#### **TOR5 – PRESENCE AND SURVIVAL IN MATRICES** 2/3

- **PEDV RNA** has been detected at low levels in the **serum** fraction of whole blood, but, to date, no data exist on the infectious virus in this matrix.
- Faecal cross-contamination of blood during collection at slaughterhouses cannot be excluded.
- It is reported that spray-drying of porcine plasma can inactivate PEDV. However, the influence of variations in spray-drying processes has not been sufficiently validated for PEDV.
- Infectious PEDV has been detected in SDPP in one study, but the origin of the infectious PEDV in SDPP is not clear (cross-contamination or inadequate spray-drying).
- The infectious virus has been detected in air collected under experimental conditions and so PEDV may be transmitted via the air for short distances.

#### **TOR5 – PRESENCE AND SURVIVAL IN MATRICES** 3/3

- Low levels of PEDV RNA have been detected in semen, but there are no data available on the presence of infectious virus in this matrix.
- There are currently **no data** available on the presence of PEDV
  - in embryos, pork meat or other porcine-derived feed components such as red blood cells, hydrolysed proteins, fat, gelatine and collagen.
- Porcine swill, particularly including untreated pig intestines, can contain infectious PEDV but there are no data available at the moment on the role of this matrix in PEDV transmission.

# **Porcine deltacoronavirus(PDCoV)**

# **TORs and CONCLUSIONS**

#### **CONCLUSIONS PDCOV TOR1 AND TOR4**

# **TOR1 – epidemiological situation**

- Diagnostic capabilities are limited in many countries and, hence, only very limited testing is carried out.
- PDCoV has only been reported from Hong Kong, US, Canada and China

# **TOR4 - impact**

- Diagnostic tools to detect PDCoV-specific antibodies have recently been developed and are currently in the process of validation
- Based on the currently available field observations from the USA, the current view is that PDCoV infections would have a lower impact than PEDV.

#### **TOR2 – PDCOV AN EMERGING DISEASE?**

**Characterization** of the new porcine **Deltacoronavirus** as an **emerging disease**, especially as regards the severity of the disease induced

An **emerging disease** is **defined by OIE** as a new occurrence of a disease, infection or infestation in an animal, causing a **significant impact** on animal or public health resulting from (1) a change of a known pathogenic agent or its spread to a new geographic area or species; or (2) a previously unrecognized pathogenic agent or disease diagnosed for the first time

At present, there is no clear evidence that PDCoV infections is causing a significant impact on animal or public health.

#### **CONCLUSIONS PDCOV TOR5**

## **TOR5 – presence and survival in matrices**

There is a lack of data on the presence and survival of PDCoV in different matrices. It could be anticipated that the presence and survival of PDCoV in different matrices is comparable to that of other intestinal porcine coronaviruses such as PEDV and TGEV.

# **PED and PDCoV**

# RECOMMENDATIONS

#### RECOMMENDATIONS

# **TOR1 – epidemiological situation**

Promote harmonized diagnostic tools for PEDV as well as for PDCoV

# **TOR3 – differences between strains**

- The genetic sequence of further recent PEDV-EU isolates should be determined to understand PEDV evolution in Europe and the possible link with PEDV-Am and/or PEDV-As strains.
- Comparative animal studies including PEDV-EU, PEDV-Am and PEDV-As strains should be performed to obtain knowledge on their differences in virulence.
- More knowledge is required regarding the cross-protection between PEDV-EU, PEDV-Am and PEDV-As strains, which could be acquired by performing cross-infection experiments.

#### RECOMMENDATIONS

# **TOR4 - impact**

The assessment of the possible impact of PEDV infection in the EU would require monitoring of the **PEDV-seroprevalence level** in Europe.

# **TOR2 – PDCoV as emerging disease**

Experimental studies are needed to obtain more knowledge on the pathogenesis and clinical signs of PDCoV infection.

#### RECOMMENDATIONS

# **TOR5 – presence and survival in matrices**

More knowledge is required to assess the importance of feed components, blood and semen in the spread of PEDV.

- Cross-contamination of any object or feed with intestinal contents and faeces from PEDV-infected pigs should be prevented.
- The influence of variations in spray-drying processes should be validated more extensively for PEDV.

#### ANNOUNCEMENT

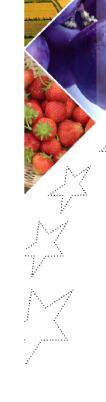

## Public consultation on small scale dairy cow farming

**Review of a description and categorization of small scale/non-conventional farms** 

in support of the ongoing scientific opinion on the welfare of dairy cows kept in small scale farms

# 8th December 2014 to 30th January 2015

- check EFSA's website, announcements
