a. Assessment:

Molecular characterisation

Study by Hoechst (Dr Arno Schulz) concerning the substrates of phosphinothricin acetyltransferase (PAT). _____ Amsterdam, 7 November 1999. Two study designs, producing opposite conclusions, namely 1. Charles J. Thompson, 1987: Characterization of the herbicide-resistance gene bar from *Streptomyces hygroscopicus*: 2. Dr Arno Schulz, 1993: L-Phosphinothricin N-Acetyltransferase - Biochemical Characterization – a report incorporated into Wehrmann 1996 (Schulz is co-author). The subject is the characterization of the enzyme phosphinothricin acetyltransferase (PAT), and in particular the specificity of the substrates. The first study concerns the reaction of phosphinothricin with acetyl co-enzyme A under the influence of PAT and compares this with a number of structural analogues of phosphinothricin (PPT). One of the analogues was L-glutamate. The products of the reaction were identified via a mass spectrogram and the equilibrium constants (affinity) determined. In addition to phosphinothricin (PPT) a number of structural analogues were tested to determine whether there was an acetylation reaction. L-glutamic acid was one of the substances investigated. Compared with PPT the affinity of most of the substances was low: one substance did not react at all. In this test, where a numerically reportable reaction occurred to an identified product (the detection threshold is not an issue here) there does not appear to be any reason to doubt that glutamic acid is a substrate of PAT.

The second study concerns the reaction of a large number of amino acids, including L-glutamic acid, which was also involved in the first study, in a reaction mix together with a 100% excess of PPT in relation to the acetyl source acetyl co-enzyme A and PAT. Products of the reaction were identified via chromatography. Even with a very large excess of L-amino acid no products of reaction with the amino acids were found. Only acetyl phosphinothricin was found. The authors concluded that PAT very specifically has only PPT as a substrate. The following criticisms can be made of this conclusion, which conflicts with that produced in the first study. (Incidentally, the first study is cited in the Bibliography to the second study): 1. No detection threshold was determined for acetylated L-glutamic acid. 2. The possibility of acetylated glutamic acid being a source of acetyl for the acetylation of PPT was ignored. This could have been tested in the study by adding acetylated glutamic acid to the reaction mix in a quantity above the detection threshold and examining whether this added quantity disappears during the reaction. Based on the results of the first study it could certainly be predicted to disappear!! 3. The study was conducted using a reaction mix in which a large excess of a competing substrate, PPT, was present. Observations with the pure amino acids were not conducted. 4. There is no discussion whatsoever of the results of the first study, in particular as to why these were so different. 5. Essentially, the authors of the second study accuse the authors of the first study of fabrication, of fraud (the first study contains a wealth of numerical

data; in the second there are no figures). In the second study this aspect is not developed satisfactorily. The background to the conclusion that PAT has only one substrate - PTT – is as follows: in herbicide-resistant (i.e. PPT-resistant) crops, PAT is present. In order to get products approved for the market the toxicity of this gene-product must be examined. Could this gene product react with the content of our GUT, e.g. with the – important – amino acid L-glutamic acid? It would cost a fortune in research to demonstrate that the dangers were minimal. For HOECHST, it seems that total denial is a better strategy! We believe that the conclusion drawn in the second study is completely unfounded and that the so-called "study" is unworthy of the name. It is an incompetent study and those persons who cite it need to be told about its incompetence. J. van der Meulen, L. Eijsten.

b. Food Safety Assessment: Toxicology

9 September 2010 Dr. Blaylock: Dangers of GMO Pesticides. Recent studies have found much higher concentrations of weed killers in these crops. This is important because weed killers and other pesticides are associated with a number of very deadly diseases, the main one being cancer. Weed killers, unlike many pesticides, extend to millions of homes, golf courses, and public facilities.

http://www.newsmxhealth.com/dr_blaylock/GMO_pesticides/2010/09/09/348541.html?s=al&promo_code=AB57-1

Press Release, January 19, 2009 Coalition against Bayer Dangers Take Glufosinate off the Market immediately! Bayer's herbicide among 22 most dangerous substances / Coalition also demands ban on glufosinate-resistant plants The Coalition against Bayer Dangers demands an immediate ban on the herbicide glufosinate and a suspension of all approvals of glufosinate-resistant crops. European Parliament members voted last week to ban pesticides classified as carcinogenic, mutagenic or toxic to reproduction. Permits for 22 substances, among them glufosinate, will not be renewed. Philipp Mimkes from the Coalition against Bayer Dangers: "Pesticides such as glufosinate that have been proven hazardous for operators, consumers and the environment must be removed from the market straight away. The EU ban on glufosinate must also have consequences for the approval of GM crops: no more permissions for glufosinate-resistant plants must be granted in the European Union!" Bayer CropScience, based in Germany, sells glufosinate under the trademarks Basta and Liberty. The substance is one of the best-selling herbicides in the world, with sales in 2007 of €241 million. Bayer is currently expanding glufosinate production capacity in Germany. A European Food Safety Authority (EFSA) evaluation states that glufosinate poses a high risk to mammals. The substance is classified as reprotoxic, with laboratory experiments causing premature birth, intra-uterine death and abortions in rats. Japanese studies show that the substance can also hamper the development and activity of the human brain. The new EU regulation declares a ban on all CRM (carcinogenic, reprotoxic and mutagenic) pesticides from categories I and II. Glufosinate is classified as falling in reprotoxic category II. Already in 2006 Swedish authorities demanded an EU-wide ban. In the U.S. and Latin America the ingredient is widely used as a "super herbicide" for genetically modified crops, mainly on rapeseed, maize, soy bean, cotton, rice and sugar beet. Bayer requested EU approval for several glufosinate-resistant plants, among them a genetically altered rice (LL Rice 62). In 2006 a similar rice (LL Rice 601) that was never approved was found in food supplies across the world and led to

the largest GM contamination scandal so far. The Coalition against Bayer Dangers also demands that BAYER publishes all studies on pesticides and chemicals. Jan Pehrke from the Coalition said: "Industry must not be allowed to hide unwelcome information. Full public access to health and environmental data about substances that are released into the environment and used on our food is necessary." For more information: • Letter to EU Ministers (2006): Act now for a ban of Bayer's glufosinate • Reject Bayer's application to import genetically modified rice into the EU <http://www.cbgnetwork.org/2785.html>

GILLES-ERIC SERALINI

GMOs in Question(s) Gilles-Eric Seralini is a university lecturer and a researcher in molecular biology. He is also the author of a book entitled OGM, Le Vrai Débat (GM foods, the real debate). He was one of the first scientists to warn the public opinion against the dangers linked to Genetically Modified Organisms (GMOs). In this interview, he reminds us of a few basic facts about GMOs and tells us about the threat they represent.

What is your current research about ? My research focuses on the intimate functioning of a cell, on the dialogue between organs and organisms, and on molecular dialogues. More specifically, I am studying molecular endocrinology and the relations between hormones/cancers and pesticides. Scientific evidence documenting the negative impacts of genetically modified (GM) foods on human and animal health and the environment

GM foods and crops were virtually excluded from the European Union in the 1990s by scientific objections and consumer concerns. But now they are once again being strongly promoted in Europe by the biotechnology industry, putting our health and environment at risk.

Scientists' warnings proven correct When GM crops and foods were first introduced in the 1990s, scientists raised concerns that genetic modification was imprecise and unpredictable. They warned: • GM could create foods that are toxic, allergenic and less nutritious than their non-GM counterparts • GM crops could damage vulnerable wild plant and animal populations

and harm biodiversity • GM plants cannot be recalled, but as living organisms will multiply, passing any damaging traits from generation to generation • GM crops could cause irreversible changes to our food supply, with serious effects on the environment and human and animal health. All these concerns have since been proven correct. Nevertheless, the European Commission continues to approve GM crops for food and animal feed (more than 24 to date) and the GM industry continues to lobby to change GM regulations in its favour. As a result, European consumers are being exposed to the risks of genetically modified organisms (GMOs) without their knowledge or consent. MORE: <http://www.gentechvrij.nl/plaatjesgen/wetenschappersnegentigond.pdf> -----
----- <http://www.aaemonline.org/gmopost.html> With the precautionary principle in mind, because GM foods have not been properly tested for human consumption, and because there is ample evidence of probable harm, the AAEM asks: Physicians to educate their patients, the medical community, and the public to avoid GM foods when possible and provide educational materials concerning GM foods and health risks. Physicians to consider the possible role of GM foods in the disease processes of the patients they treat and to document any changes in patient health when changing from GM food to non-GM food. Our members, the medical community, and the independent scientific community to gather case studies potentially related to GM food consumption and health effects, begin epidemiological research to investigate the role of GM foods on human health, and conduct safe methods of determining the effect of GM foods on human health. For a moratorium on GM food, implementation of immediate long term independent safety testing, and labeling of GM foods, which is necessary for the health and safety of consumers. (This statement was reviewed and approved by the Executive Committee of the American Academy of Environmental Medicine on May 8, 2009.) Submitted by Amy Dean, D.O. and Jennifer Armstrong, M.D.

An insecticide used in genetically modified (GM) crops grown extensively in the United States and other parts of the world has leached into the water of the surrounding environment.

The insecticide is the product of a bacterial gene inserted into GM maize and other cereal crops to protect them against insects such as the European corn borer beetle. Scientists have detected the insecticide in a significant number of streams draining the great corn belt of the American mid-West.

The researchers detected the bacterial protein in the plant detritus that was washed off the corn fields into streams up to 500 metres away. They are not yet able to determine how significant this is in terms of the risk to either human health or the wider environment.

"Our research adds to the growing body of evidence that corn crop byproducts can be dispersed throughout a stream network, and that the compounds associated with genetically modified crops, such as insecticidal proteins, can enter nearby water bodies," said Emma Rosi-Marshall of the Cary Institute of Ecosystem Studies in Millbrook, New York.

GM crops are widely cultivated except in Britain and other parts of Europe. In 2009, more than 85 per cent of American corn crops were genetically modified to either repel pests or to be tolerant to herbicides used to kill weeds in a cultivated field.

The GM maize, or corn as it is called in the US, has a gene from the bacterium *Bacillus thuringiensis* (Bt) inserted into it to repel the corn borer beetle. The Bt gene produces a protein called Cry(12A)b which has insecticidal properties.

The study, published in the journal *Proceedings of the National Academy of Science*, analysed 217 streams in Indiana. The scientists found 86 per cent of the sites contained corn leaves, husks, stalks or cereal cobs in their channels and 13 per cent contained detectable levels of the insecticidal Cry(12A)b proteins.

"The tight linkage between corn fields and streams warrants further research into how corn byproducts, including Cr(12A)b insecticidal proteins, potentially impact non-target ecosystems, such as streams and wetlands," Dr Rosi-Marshall said.

All of the stream sites with detectable insecticidal proteins were located within 500 metres of a corn field. The ramifications are vast just in Iowa, Illinois, and Indiana, where about 90 per cent of the streams and rivers – some 159,000 miles of waterways – are also located within 500 metres of corn fields.

After corn crops are harvested, a common agricultural practice is to leave discarded plant material on the fields. This "no-till" form of agriculture minimises soil erosion, but it then also sets the stage for corn byproducts to enter nearby stream channels. --- --- 2. Insecticides from genetically modified corn present in adjacent streams

[IMAGE: Recognizing the tight linkage between agricultural practices and adjacent aquatic ecosystems, like headwater streams, will help ensure the health and productivity of both. Click here for more information.]

In a paper published this week in the *Proceedings of the National Academy of Sciences*, Cary Institute aquatic ecologist Dr. Emma Rosi-Marshall and colleagues report that streams throughout the Midwestern Corn Belt are receiving insecticidal proteins that originate from adjacent genetically modified crops. The protein enters streams through runoff and when corn leaves, stalks, and plant parts are washed into stream channels.

Genetically-modified plants are a mainstay of large-scale agriculture in the American Midwest, where corn is a dominant crop. In 2009, more than 85% of U.S. corn crops were genetically modified to repel pests and/or resist herbicide exposure. Corn engineered to release an insecticide that wards off the European corn borer, commonly referred to as Bt

corn, comprised 63% of crops. The tissue of these plants has been modified to express insecticidal proteins, one of which is commonly known as Cry1Ab.

Following an assessment of 217 stream sites in Indiana, the paper's authors found dissolved Cry1Ab proteins from Bt corn present in stream water at nearly a quarter of the sites, including headwater streams. Eighty-six percent of the sampled sites contained corn leaves, husks, stalks, or cobs in their channels; at 13% of these sites corn byproducts contained detectable Cry1Ab proteins. The study was conducted six months after crop harvest, indicating that the insecticidal proteins in crop byproducts can persist in the landscape.

Using these data, U.S. Department of Agriculture land cover data, and GIS modeling, the authors found that all of the stream sites with detectable Cry1Ab insecticidal proteins were located within 500 meters of a corn field. Furthermore, given current agricultural land use patterns, 91% percent of the streams and rivers throughout Iowa, Illinois, and Indiana —some 159,000 miles of waterways—are also located within 500 meters of corn fields.

Rosi-Marshall comments, "Our research adds to the growing body of evidence that corn crop byproducts can be dispersed throughout a stream network, and that the compounds associated with genetically-modified crops, such as insecticidal proteins, can enter nearby water bodies."

After corn crops are harvested, a common agricultural practice is to leave discarded plant material on the fields. This "no-till" form of agriculture minimizes soil erosion, but it also sets the stage for corn byproducts to enter nearby stream channels.

Rosi-Marshall concludes, "The tight linkage between corn fields and streams warrants further research into how corn byproducts, including Cr1Ab insecticidal proteins, potentially impact non-target ecosystems, such as streams and wetlands." These corn byproducts may alter the health of freshwaters. Ultimately, streams that originate in the Corn Belt drain into the Mississippi River and the Great Lakes.

Transgenic crops' built-in pesticide found to be contaminating waterways Tom Laskawy GRIST, 29 September 2010 <http://www.grist.org/article/food-2010-09-29-transgenic-crops-found-to-be-contaminating-waterways/>

One of the main arguments offered in support of the wide use of genetically engineered crops is that they reduce overall pesticide use. This is particularly the case with Monsanto's "Bt" line of corn, soy, and cotton seeds, which are able to produce their own pesticide, a "natural"

toxin from genes of the bacteria *Bacillus thuringiensis*. Ironically, commercial pesticide derived from Bt also happens to be one of the only chemical pesticides approved for use in organic agriculture, because it's produced through a biological process.

Biotechnology companies thus consider Bt seeds some of their most "eco-friendly" products. In theory, farmers don't have to spray pesticide as much or as often on these crops, and therefore pesticide runoff into waterways is much less of a concern. Well, after years of denial, Monsanto finally admitted recently that superbugs, or pests that have evolved to be able to eat the Bt crops, are a real and growing concern. And now, researchers at the University from Notre Dame have shown that the Bt from genetically engineered maize is polluting waterways in Indiana (the study area). They found Bt toxin in almost 25 percent of streams they tested, and all the streams that tested positive were within 1,500 feet from a cornfield.

Bt gets into streams and rivers by leaching out of crop debris left on fields through the now-ubiquitous industrial "no-till" farming technique, in which fields aren't plowed after harvest so as to prevent soil erosion. As a result, leaves and stalks get washed into streams through large-scale farms' irrigation canals: the Notre Dame scientists found such debris in almost 90 percent of streams near cornfields. And while the Bt levels detected weren't shockingly high, the tests were performed six months after harvest. The debris had been sitting in the streams and leaching Bt pesticide into the water for quite a while.

The fun part? No one has any idea yet of the effects of long-term, low-dose exposure to Bt on fish and wildlife. Perhaps it's high time somebody did a study on that since, as the researchers dryly observed, the presence of Bt toxin "may be a more common occurrence in watersheds draining maize-growing regions than previously recognized." Apparently.

So. Not only do genetically engineered crops have worse yields than conventionally bred crops, cost more, lead to pesticide resistance, contaminate other plants with their transgenes, possibly cause allergies and even organ damage, but now we also learn that the plants themselves are possibly poisonous to the environment.

These kinds of genetically engineered seeds keep being touted as the only way we're going to feed the world. Isn't it about time we started investing in less toxic alternatives?

Corn engineered to release an insecticide that wards off the European corn borer, commonly referred to as Bt corn, comprised 63% of crops. The tissue of these plants has been modified to express insecticidal proteins, one of which is commonly known as Cry1Ab.

Following an assessment of 217 stream sites in Indiana, the paper's authors found dissolved Cry1Ab proteins from Bt corn present in stream water at nearly a quarter of the sites, including headwater streams. Eighty-six percent of the sampled sites contained corn leaves, husks, stalks, or cobs in their channels; at 13% of these sites corn byproducts contained detectable Cry1Ab proteins. The study was conducted six months after crop harvest, indicating that the insecticidal proteins in crop byproducts can persist in the landscape.

Using these data, U.S. Department of Agriculture land cover data, and GIS modeling, the authors found that all of the stream sites with detectable Cry1Ab insecticidal proteins were located within 500 meters of a corn field. Furthermore, given current agricultural land use patterns, 91% percent of the streams and rivers throughout Iowa, Illinois, and Indiana —some 159,000 miles of waterways—are also located within 500 meters of corn fields.

Rosi-Marshall comments, "Our research adds to the growing body of evidence that corn crop byproducts can be dispersed throughout a stream network, and that the compounds associated with genetically-modified crops, such as insecticidal proteins, can enter nearby water bodies."

After corn crops are harvested, a common agricultural practice is to leave discarded plant material on the fields. This "no-till" form of agriculture minimizes soil erosion, but it also sets the stage for corn byproducts to enter nearby stream channels.

Rosi-Marshall concludes, "The tight linkage between corn fields and streams warrants further research into how corn byproducts, including Cr1Ab insecticidal proteins, potentially impact non-target ecosystems, such as streams and wetlands." These corn byproducts may alter the health of freshwaters. Ultimately, streams that originate in the Corn Belt drain into the Mississippi River and the Great Lakes.

Transgenic crops' built-in pesticide found to be contaminating waterways Tom Laskawy GRIST, 29 September 2010 <http://www.grist.org/article/food-2010-09-29-transgenic-crops-found-to-be-contaminating-waterways/>

One of the main arguments offered in support of the wide use of genetically engineered crops is that they reduce overall pesticide use. This is particularly the case with Monsanto's "Bt" line of corn, soy, and cotton seeds, which are able to produce their own pesticide, a "natural" toxin from genes of the bacteria *Bacillus thuringiensis*. Ironically, commercial pesticide derived from Bt also happens to be one of the only chemical pesticides approved for use in organic agriculture, because it's produced through a biological process.

Biotechnology companies thus consider Bt seeds some of their most "eco-friendly" products. In theory, farmers don't have to spray pesticide as much or as often on these crops, and therefore pesticide runoff into waterways is much less of a concern. Well, after years of denial, Monsanto finally admitted recently that superbugs, or pests that have evolved to be able to eat the Bt crops, are a real and growing concern. And now, researchers at the University from Notre Dame have shown that the Bt from genetically engineered maize is polluting waterways in Indiana (the study area). They found Bt toxin in almost 25 percent of streams they tested, and all the streams that tested positive were within 1,500 feet from a cornfield.

Bt gets into streams and rivers by leaching out of crop debris left on fields through the now-ubiquitous industrial "no-till" farming technique, in which fields aren't plowed after harvest so as to prevent soil erosion. As a result, leaves and stalks get washed into streams through large-scale farms' irrigation canals: the Notre Dame scientists found such debris in almost 90 percent of streams near cornfields. And while the Bt levels detected weren't shockingly high, the tests were performed six months after harvest. The debris had been sitting in the streams and leaching Bt pesticide into the water for quite a while.

The fun part? No one has any idea yet of the effects of long-term, low-dose exposure to Bt on fish and wildlife. Perhaps it's high time somebody did a study on that since, as the researchers dryly observed, the presence of Bt toxin "may be a more common occurrence in watersheds draining maize-growing regions than previously recognized." Apparently.

So. Not only do genetically engineered crops have worse yields than conventionally bred crops, cost more, lead to pesticide resistance, contaminate other plants with their transgenes, possibly cause allergies and even organ damage, but now we also learn that the plants themselves are possibly poisonous to the environment.

These kinds of genetically engineered seeds keep being touted as the only way we're going to feed the world. Isn't it about time we started investing in less toxic alternatives?

..... Website: <http://www.gmwatch.org>

4. Conclusions and recommendations

As GM crops (including also GM carnations and other GM flowers with altered colours) and the herbicides used on them pose so many dangers to human, animal and environmental health, serious disadvantages, which have been brought to light and continue to be brought to light over and over again by validated peer-reviewed research, we urge you not to place these crops on the market and not to grow them in the fields. Preference should be given to organic farming and to local products, which have been grown safely for centuries.

5. Others

For the consumer there are no advantages. Disadvantages are not mentioned. There are too many to mention. Thus, there are as yet only disadvantages for the consumer, such as adverse effects on health:

- Retired scientist Dr. Arpad Pusztai answers “Yes” to the following question in this interview: “Do you believe that scientific research will conclusively show that GM foods pose significant health risks?” http://www.organicconsumers.org/articles/article_18101.cfm

US Opposition to GMOs Gathers Momentum: Scientists and physicians in the heartland of genetic modification are alerting policy-makers and the public to the dangers of GM crops. http://www.i-sis.org.uk/US_Opposition_to_GMOs.php

But nothing on this is reported to the consumer.

American doctors are already prescribing their patients non-GM diets (PDF)! <http://www.gentechvrij.nl/plaatjesgen/semspillingthebeans.pdf>

After an appeal from the American Academy Of Environmental Medicine <http://www.aaemonline.org/gmopost.html>, Irish doctors have also called for a moratorium on GM foods (<http://www.ideaireland.org/gmfood.htm>), Irish Medical Times, 12 June 2009

6. Labelling proposal

No GM crops, and therefore no labelling necessary!

Organisation: The European GMO-free Citizens

Country: The Netherlands

Type: Non Profit Organisation

a. Assessment:

Molecular characterisation

See "5 others" and our previous comment, which you must include.

Comparative analysis (for compositional analysis and agronomic traits and GM phenotype)

See "5 others" and our previous comment, which you must include.

b. Food Safety Assessment:

Toxicology

See "5 others" and our previous comment, which you must include.

Allergenicity

See "5 others" and our previous comment, which you must include.

Nutritional assessment

See "5 others" and our previous comment, which you must include.

Others

See "5 others" and our previous comment, which you must include.

3. Environmental risk assessment

See "5 others" and our previous comment, which you must include.

4. Conclusions and recommendations

GM food is to be removed immediately from all shelves and all soils, because of the great danger they are to our planet, health, and the health of the animals that live on this earth.

This Supermarket "Health Food" Killed These Baby Rats in Three Weeks Posted By Dr. Mercola | October 04 2010 | 13,182 views Article By Jeffrey Smith

Arpad Pusztai

Biologist Arpad Pusztai had more than 300 articles and 12 books to his credit and was the world's top expert in his field.

But when he accidentally discovered that genetically modified (GM) foods are dangerous, he became the biotech industry's bad-boy poster child, setting an example for other scientists thinking about blowing the whistle.

In the early 1990s, Dr. Pusztai was awarded a \$3 million grant by the UK government to design the system for safety testing genetically modified organisms (GMOs). His team included more than 20 scientists working at three facilities, including the Rowett Institute in Aberdeen, Scotland, the top nutritional research lab in the UK, and his employer for the previous 35 years.

The results of Pusztai's work were supposed to become the required testing protocols for all of Europe. But when he fed supposedly harmless GM potatoes to rats, things didn't go as planned.

Within just 10 days, the animals developed potentially pre-cancerous cell growth, smaller brains, livers, and testicles, partially atrophied livers, and damaged immune systems. Moreover, the cause was almost certainly side effects from the process of genetic engineering itself. In other words, the GM foods on the market, which are created from the same process, might have similar affects on humans.

With permission from his director, Pusztai was interviewed on TV and expressed his concerns about GM foods. He became a hero at his institute -- for two days.

Then came the phone calls from the pro-GMO prime minister's office to the institute's director. The next morning, Pusztai was fired. He was silenced with threats of a lawsuit, his team was dismantled, and the protocols never implemented. His Institute, the biotech industry, and the UK government, together launched a smear campaign to destroy Pusztai's reputation.

Eventually, an invitation to speak before Parliament lifted his gag order and his research was published in the prestigious Lancet. No similar in-depth studies have yet tested the GM foods eaten every day by Americans.

Irina Ermakova Irina Ermakova, a senior scientist at the Russian National Academy of Sciences, was shocked to discover that more than half of the baby rats in her experiment died within three weeks. She had fed the mothers GM soy flour purchased at a supermarket. The babies from mothers fed natural non-GMO soy, however, only suffered a 10% death rate. She repeated her experiment three times with similar results.

Dr. Ermakova reported her preliminary findings at a conference in October 2005, asking the scientific community to replicate her study. Instead, she was attacked and vilified. Her boss told her to stop doing anymore GM food research. Samples were stolen from her lab, and a paper was even set fire on her desk. One of her colleagues tried to comfort her by saying, "Maybe the GM soy will solve the overpopulation problem."

Of the mostly spurious criticisms leveled at Ermakova, one was significant enough to raise doubts about the cause of the deaths. She did not conduct a biochemical analysis of the feed. Without it, we don't know if some rogue toxin had contaminated the soy flour. But more recent events suggest that whatever caused the high infant mortality was not unique to her one bag of GM flour.

In November 2005, the supplier of rat food to the laboratory where Ermakova worked began using GM soy in the formulation. All the rats were now eating it. After two months, Ermakova asked other scientists about the infant mortality rate in their experiments. It had skyrocketed to over 55 percent.

It's been four years since these findings were reported. No one has yet repeated Ermakova's study, even though it would cost just a few thousand dollars.

Andrés Carrasco Embryologist Andrés Carrasco told a leading Buenos Aires newspaper about the results of his research into Roundup, the herbicide sold in conjunction with Monsanto's genetically engineered Roundup Ready crops.

Dr. Carrasco, who works in Argentina's Ministry of Science, said his studies of amphibians suggest that the herbicide could cause defects in the brain, intestines, and hearts of fetuses. Moreover, the amount of Roundup used on GM soy fields was as much as 1,500 times greater than that which created the defects.

Tragically, his research had been inspired by the experience of desperate peasant and indigenous communities who were suffering from exposure to toxic herbicides used on the GM soy fields throughout Argentina.

According to an article in Grain, the biotech industry "mounted an unprecedented attack on Carrasco, ridiculing his research and even issuing personal threats." In addition, four men arrived unannounced at his laboratory and were extremely aggressive, attempting to interrogate Carrasco and obtain details of his study. "It was a violent, disproportionate, dirty reaction," he said. "I hadn't even discovered anything new, only confirmed conclusions that others had reached."

Argentina's Association of Environmental Lawyers filed a petition calling for a ban on Roundup, and the Ministry of Defense banned GM soy from its fields.

Judy Carman Epidemiologist Judy Carman used to investigate outbreaks of disease for a state government in Australia. She knows that health problems associated with GM foods might be impossible to track or take decades to discover. Moreover, the superficial, short-term animal feeding studies usually do not evaluate "biochemistry, immunology, tissue pathology, gut function, liver function, and kidney function" and are too short to test for cancer or reproductive or child health.

Dr. Carman has critiqued the GMO approval process on behalf of the Public Health Association of Australia and speaks openly about her concerns. As a result, she is repeatedly attacked. Pro-GM scientists threatened disciplinary action through her Vice-Chancellor, and circulated a defamatory letter to government and university officials.

Carman was awarded a grant by the Western Australia government to conduct some of the few long-term animal feeding studies on GMOs. Apparently concerned about what she might find, GMO advocates wrote letters to the government demanding that the grant be withdrawn. One scientist tried to convince the Western Australia Agriculture minister that sufficient safety research had been conducted and he should therefore cancel the grant.

As his evidence, however, he presented a report summarizing only 60 GMO animal feeding studies -- an infinitesimal amount of research to justify exposing the entire population to GM foods.

A closer investigation, however, revealed that most of the 60 were not safety studies at all. They were production studies, measuring, for example, the animals' carcass weight. Only 9 contained data applicable to human health. And 6 of the 9 showed adverse effects in animals that ate GM feed!

Furthermore, there were several other studies with adverse findings that were mysteriously missing from the compilation. Carman points out that the report "does not support claims that GM crops are safe to eat. On the contrary, it provides evidence that GM crops may be harmful to health."

When the Western Government refused to withdraw the grant, opponents successfully interfered with Carman's relationship with the university where she was to do the research.

Terje Traavik Prominent virologist Terje Traavik presented preliminary data at a February 2004 meeting at the UN Biosafety Protocol Conference, showing that:

1. Filipinos living next to a GM cornfield developed serious symptoms while the corn was pollinating; 2. Genetic material inserted into GM crops transferred to rat organs after a single meal; and 3. Key safety assumptions about genetically engineered viruses were overturned, calling into question the safety of using these viruses in vaccines. The biotech industry mercilessly attacked Dr. Traavik. Their excuse? -- he presented unpublished work. But presenting preliminary data at professional conferences is a long tradition in science, something that the biotech industry itself relied on in 1999 to try to counter the evidence that butterflies were endangered by GM corn.

Ironically, three years after attacking Traavik, the same biotech proponents sharply criticized a peer-reviewed publication for not citing unpublished data that had been presented at a conference. The paper shows how the runoff of GM Bt corn into streams can kill the “caddis fly,” which may seriously upset marine ecosystems. The study set off a storm of attacks against its author, ecologist Emma Rosi-Marshall, which Nature described in a September 2009 article as a “hail of abuse.”

Companies Prevent Studies on Their GM Crops When Ohio State University plant ecologist Allison Snow discovered problematic side effects in GM sunflowers, Pioneer Hi-Bred International and Dow AgroSciences blocked further research by withholding GM seeds and genes.

After Marc Lappé and Britt Bailey found significant reductions in cancer-fighting isoflavones in Monsanto’s GM soybeans, the seed seller, Hartz, told them they could no longer provide samples.

Research by a plant geneticist at a leading US university was also thwarted when two companies refused him GM corn. In fact, almost no independent studies are conducted that might find problems. According to a scathing opinion piece in an August 2009 Scientific American,

“Agritech companies have given themselves veto power over the work of independent researchers ... Only studies that the seed companies have approved ever see the light of a peer-reviewed journal.”

A group of 24 corn insect scientists protested this restriction in a letter submitted to the Environmental Protection Agency. They warned that the inability to access GM seeds from biotech companies means there can be no truly independent research on the critical questions. The scientists, of course, withheld their identities for fear of reprisals from the companies.

Restricted access is not limited to the US. When a Japanese scientist wanted to conduct animal feeding studies on the GM soybeans under review in Japan, both the government and the bean’s maker DuPont refused to give him any samples. Hungarian Professor Bela Darvas discovered that Monsanto’s GM corn hurt endangered species in his country. Monsanto immediately shut off his supplies.

Dr. Darvas later gave a speech on his preliminary findings and discovered that a false and incriminating report about his research was circulating. He traced it to a Monsanto public relations employee, who claimed it mysteriously appeared on her desk -- so she faxed it out.

GMO Contamination: Don't Ask and Definitely Don't Tell In 2005, a scientist had gathered seed samples from all over Turkey to evaluate the extent of contamination by GM varieties. According to the Turkish Daily News, just before her testing was complete, she was reassigned to another department and access to her lab was denied.

The unexpected transfer may have saved this Turkish scientist from an even worse fate, had she discovered and reported contamination.

Ask Ignacio Chapela, a microbial ecologist from UC Berkeley. In 2001, he discovered that the indigenous corn varieties in Mexico -- the source of the world's genetic diversity for corn— had become contaminated through cross pollination with GM varieties.

The government had a ban against GM corn to prevent just this possibility, but apparently US corn imported for food had been planted nonetheless.

Dr. Chapela submitted the finding to Nature, and as a courtesy that he later regretted, informed the Mexican government about the pending publication. He was called in to meet with a furious Director of the Commission of Biosafety and GMOs. Chapela's confirmation of contamination would hinder introduction of GM corn. Therefore the government's top biotech man demanded that he withdraw his article. According to Chapela, the official intimidated and threatened him, even implying, "We know where your children go to school."

When a traumatized Chapela still did not back down, the Underminister for Agriculture later sent him a fax claiming that because of his scientific paper, Chapela would be held personally responsible for all damages caused to agriculture and to the economy in general.

The day Chapela's paper was published, Mary Murphy and Andura Smetacek began posting messages to a biotechnology listserv called AgBioWorld, distributed to more than 3,000 scientists. They falsely claimed that Chapela was biased, that his paper had not been peer-reviewed, that Chapela was "first and foremost an activist," and his research was published in collusion with environmentalists. Soon, hundreds of other messages appeared, repeating or embellishing the accusations. The listserv launched a petition and besieged Nature with a worldwide campaign demanding retraction.

UC Berkeley also received letters from all over the world trying to convince them not to grant Chapela tenure. He had overwhelming support by his college and department, but the international biotech lobby was too much. Chapela's tenure was denied. After he filed a lawsuit, the university eventually reversed its decision.

When investigators later analyzed the email characteristics sent by agitators Mary Murphy and Andura Smetacek, the two turned out not to be the average citizens they claimed. According to the Guardian, both were fabricated names used by a public relations firm that worked for Monsanto. Some of Smetacek's emails also had the internet protocol address of gatekeeper2.monsanto.com -- the server owned by Monsanto.

Science and Debate is Silenced The attacks on scientists have taken its toll. According to Dr. Chapela, there is a de facto ban on scientists "asking certain questions and finding certain results." He says, "It's very hard for us to publish in this field. People are scared." He told Nature that young people "are not going into this field precisely because they are discouraged by what they see."

New Zealand Parliament member Sue Kedgley told a Royal Commission in 2001: "Personally I have been contacted by telephone and e-mail by a number of scientists who have serious

concerns about aspects of the research that is taking place ... and the increasingly close ties that are developing between science and commerce, but who are convinced that if they express these fears publicly ... or even if they asked the awkward and difficult questions, they will be eased out of their institution.”

University of Minnesota biologist Phil Regal testified before the same Commission, “I think the people who boost genetic engineering are going to have to do a mea culpa and ask for forgiveness, like the Pope did on the inquisition.” Sue Kedgley has a different idea. She recommends we “set up human clinical trials using volunteers of genetically engineered scientists and their families, because I think they are so convinced of the safety of the products that they are creating and I’m sure they would very readily volunteer to become part of a human clinical trial.”
